

The main unrealistic and significant difference between the initial DMP and the final DMP is that, it was mentioned in initial DMP that, the dataset has approximately 340,000 and was around 14 MB in size. The actual dataset contains 8,358 records. The initial promised figure 340,000 was approximate estimate, it was confused with the full UK national STATS19 dataset. The actual dataset is much smaller compared to the claimed dataset. It is actually a subset of the initially mentioned one. This claim was never achievable.

The wrong input license was mentioned. The initial DMP claimed "The input dataset is legally shared and openly stored in a public repository with the license CC BY 4.0." The license of the source data in the final DMP is found UK Open Government License v3.0(OGL v3.0). It was not under CC BY 4.0

Writing the final DMP shows that why it was named initial DMP, initial DMP was full of hand waving.

In the initial DMP it was mentioned that outputs will be available in a cloud platform after the end of the project. In the final DMP the DOIs of real cloud platform of TUWRD is present. The DOIs present in the DMP supports that the deposits are completed with filling in every metadata field and linking the records to each other. Some never predicted problems have been surfaced during doing the project. Most memorably, an HTTP 500 error happened during the DB Repo test instance when trying to mint a DataCite DOI. The initial version has no room for that kind of real-world detail. In the initial DMP everything was treated under CC BY 4.0 and never mentioned the software license. In the final version input data fall under the license of OGL v3.0, the code under MIT, and the generated output is under CC BY 4.0

In the metadata section is where the gap is the largest. In the initial version it is mentioned that documentation would include Title, Publisher, Year, License, format and update date also includes a README. In the final version it is required five different artefacts (RO-Crate, CodeMeta, FAIR4ML, Croissant and a Model Card), and top of that mapping every one of the 69 database was ontologically implemented with concepts in schema.org, GeoSPARQL, and W3C WGS84. None of this was mentioned in the initial DMP.

The same pattern shows up in the data quality section. In the initial DMP it was mentioned that ensuring the right data and eliminating duplicate values from the CSV. In the final version had to describe a 3NF relational schema across 19 tables.

The final DMP provides every claim backed by something concrete with details, a DOI, a license URL, a metric, a schema, a metadata file rather than sentence describing in the initial DMP
